

ABSTRACT

A system for deterring an attack and adding with identification and apprehension of an attacker is disclosed. A vessel containing materials capable of leaving stain, odor, or other markings on the attacker and the victim are employed. Comparison of the materials found on the victim and on the attacker will help establish the connection between the two and aid in the positive identification of the attacker. The system further provides for an audio and light alarm as additional ways for the victim to discourage the attacker. Also included is a tool that will aid the victim in escaping from the attacker's vehicle or other surroundings and a device that will help attract attention to the victim and the attacker. Alternatively, miniature devices are employed that remove samples of the attackers skin, bone, hair, tissue or bodily fluids and store the same. Subsequent analysis of these samples enables identification of the attacker. Similar devices are also employed to lodge themselves into attacker's skin. These devices contain unique codes that can be employed to identify the attacker. As a further aid in victim rescue and attacker capture, a radio frequency identification device is included, further improving the chances for finding the victim and the attacker.

Disclosure Documents for Patent Application No. 10/263458, Filed October 2, 2002

The following disclosure documents are cross referenced to this application and their contents are incorporated herein:
